

Reflection Analysis Report

Analyzed file: reflection_only.txt

The reflection coefficient (S11) describes how much of the input signal is reflected back from the antenna instead of being radiated.

- A value below -10 dB is generally considered acceptable for matching, meaning that less than 10% of the power is reflected.
- The frequency range where reflection remains below -10 dB defines the antenna's effective operating bandwidth.
- Sharp dips indicate resonances where the antenna is well matched.

Key Results:

- Minimum reflection: -400.00 Reflection (dB) at 5.00 GHz
- Frequency range analyzed: 5.00 – 9.00 GHz
